10 Why Work With DIBA

Tokenization Extends the Bitcoin Promise.

Bitcoin established a proven framework for peer-to-peer value transfer without reliance on centralized intermediaries. Tokenization builds upon this architecture. By utilizing this infrastructure, markets can migrate the instruments that underpin the global economy — bonds, equities, credit, and real assets — to a more efficient settlement rail.

The access problem is structural. Approximately 80–82% of Americans have no meaningful exposure to institutional-grade financial instruments. Globally, this exclusion affects the vast majority of the population. This is not driven by investor preference, but by the operational limitations of legacy capital markets.

80–82%

Americans without meaningful access to institutional financial instruments · Fed Survey of Consumer Finances

99.75%

Of the global population historically excluded from institutional capital markets.

\$50–80B

Estimated addressable annual friction (reconciliation, settlement lag, intermediary fees).

Every legacy financial instrument that migrates to a programmable, atomic-settlement rail eliminates a layer of operational cost. Moving even 5% of the \$400 trillion global capital stack onto Bitcoin rails

represents a \$20 trillion market — larger than any single asset class created in the last twenty years.

"The stablecoin sector alone could grow tenfold by 2030."

— U.S. Treasury Secretary Scott Bessent, Treasury Market Conference, 2025

EVM Infrastructure Has a Structural Flaw Institutional Capital Cannot Ignore.

After Bitcoin, Ethereum introduced programmable electronic value. The experiment yielded a large ecosystem. It also generated a body of evidence indicating that the design philosophy of placing contract logic in a shared, public execution environment accessible to every participant carries risks that scale with the size of the system.

Re-entrancy attacks, oracle manipulation, maximal extractable value, sandwich attacks, and bridge exploits are not isolated vulnerabilities awaiting patches. They are predictable consequences of the architecture. The empirical data reflects this clearly.

\$9.8B+ Lost to EVM/cross-chain exploits since 2020, including \$1.5B Bybit & \$293M KelpDAO · DeFiLlama	\$4.1B+ Stolen from bridges and cross-chain infrastructure, 2021–2026 · Chainalysis	1,000+ Documented DeFi exploits, 2020–2026 · Immunefi	0 Successful base-layer breaches on Bitcoin in 15 years
--	---	---	---

SELECTED MAJOR EVM EXPLOITS, 2016–2026

- 2016 **The DAO** : \$60M. Re-entrancy attack; Ethereum hard fork required.
- 2020 **bZx Flash Loan** : \$25M. Oracle manipulation via flash loan.
- 2021 **Poly Network** : \$610M. Cross-chain bridge logic exploit.
- 2022 **Ronin Bridge** : \$625M. Lazarus Group validator key compromise.
- 2022 **Wormhole** : \$320M. Signature verification bypass on Solana bridge.
- 2023 **Euler Finance** : \$197M. Flash loan and donation attack on lending protocol.
- 2024 **Radiant Capital** : \$50M. Malware-signed multi-sig transactions.
- 2025 **Bybit Exchange** : \$1.5B. Largest single crypto theft on record; Lazarus Group compromised Safe multisig UI to drain ETH cold wallet.
- 2026 **Kelp DAO (rsETH)** : \$293M. Lazarus Group (TraderTraitor) poisoned LayerZero RPC nodes via DDoS and injected a fraudulent cross-chain message; 116,500 rsETH drained from bridge.
- 2026 **Aave: Emergency Freeze** : Contagion from Kelp DAO; Aave governance force-froze all rsETH collateral markets to prevent cascading bad debt across the lending protocol.

RISK VECTOR	EVM / SOLIDITY	RGB ON BITCOIN
Smart contract exploits	\$6.5B+ lost, 2020–2025	No onchain contract execution
Bridge risk	\$3.8B stolen, 2021–2025	No bridges required
MEV / sandwich attacks	Systemic and measurable	Structurally impossible
Oracle manipulation	Multiple \$100M+ incidents	Not applicable
Re-entrancy	DAO hack: \$60M (2016)	Not applicable
Base-layer exploit record	Multiple consensus bugs across chains	Zero in 15 years
Settlement finality	Probabilistic (reorganizations possible)	Bitcoin proof-of-work finality
Position privacy	Public mempool exposure	Client-side validation only

Settlement Infrastructure Requires an Uncompromising Base Layer.

Institutions evaluate settlement infrastructure based on predictability, security history, and counterparty risk profiles. Bitcoin provides a fifteen-year operational history without a base-layer security breach. For institutional risk committees, this represents the most tested settlement layer available.

Every component settles atomically on Bitcoin L1. No bridges. No trusted intermediaries.

01

Deterministic Settlement

RGB contracts settle on Bitcoin UTXOs. No bridge operator, no validator committee that can be censored or reorganised out of existence. Settlement is final.

02

T+0 on Everything

Both legs of every trade settle in a single Bitcoin transaction. The buyer receives the asset. The seller receives payment. Either it happens completely, or it does not happen at all.

03

Regulatory-Grade Privacy

Contract state is validated client-side by the asset holder. Only the cryptographic commitment goes onchain. Investor positions are not broadcast to a public mempool.

04

Fifteen Years. No Breach.

Bitcoin has never suffered a successful base-layer exploit. Every EVM-compatible chain in production today has experienced either a consensus bug, a critical client vulnerability, or a catastrophic contract loss at scale.

05

Programmable Without Compromise

RGB enables waterfall payments, subscription mechanics, maturity triggers, and KYC/AML gating. These features are validated off-chain by the parties to the contract, while the blockchain records only the final cryptographic commitment.

Client-Validated Contracts on Bitcoin.

RGB represents a decade of development aimed at creating private, scalable smart contract protocols that utilize Bitcoin for settlement without requiring consensus changes or compromising network efficiency.

"Peter Todd's single-use seal primitives cryptographically anchor every token and asset state to a Bitcoin UTXO. Validation is private. Settlement is on Bitcoin."

Source: RGB Protocol (originating from single-use seal commitments)

Each state transition is validated client-side by the recipient, rather than by miners, validators, or a network of nodes maintaining a shared ledger. The blockchain records only a cryptographic commitment. The asset logic can systematically handle complex contractual demands: waterfall distributions, maturity triggers, investor gating, and transfer restrictions, with all execution occurring off-chain.

HOW AN RGB ASSET TRANSFER WORKS

1

Issuer defines asset schema

RGB contract written, anchored to a Bitcoin UTXO

2

Recipient shares a blinded UTXO

Recipient generates a blind seal with no public address broadcast

3

State transition constructed off-chain

Sender builds transition, validated privately by both parties

4

Commitment posted to Bitcoin

Single OP_RETURN or Taproot output commits the state transition

5

Bitcoin block confirms

Finality inherits Bitcoin's proof-of-work (T+0 relative to block confirmation)

6

Lightning routing (optional)

For sub-second settlement, RGB transfers route through Lightning channels at near-zero cost

Client-Side Validation

Validation by the asset holder, not the network

Lightning

Near-instant settlement via Lightning Network routing

No Bridges

No cross-chain trust.
No bridge operator risk.

UTXO-Anchored

Every asset state cryptographically bound to a Bitcoin UTXO

The Largest Smart Contract Use Case Is Moving to Bitcoin Rails.

Stablecoins represent a primary use case for smart contracts on EVM chains. Tether, with over \$118 billion USDT in circulation as of Q1 2026, has initiated native USDT issuance on Bitcoin via RGB. This represents a significant institutional shift toward Bitcoin settlement infrastructure.

\$118B+ USDT in circulation, Q1 2026 · Tether Treasury	48% Growth in global stablecoin transaction volume, 2023–2024 · Visa Onchain	30% Month-over-month stablecoin growth on Stripe, H1 2025	10× Projected stablecoin sector growth by 2030 · U.S. Treasury

STABLECOIN ADOPTION RATE BY BUSINESS SEGMENT (% REPORTING CURRENT USE)

Source: Stripe Global Survey of ~2,000 business leaders, 2025. Stripe internal payment volume data H1 2025.

"70% of customers paying in stablecoins on Stripe are net-new customers. For all other payment methods, that figure is 30%. The demand was always there. The rail was missing."

Source: Stripe Research, 2025

Tokenization Is Real. Bitcoin Is Still Early. That Is the Opportunity.

The tokenization of real-world assets is not speculative — it is already happening, predominantly on EVM-based infrastructure. Tokenised securities have crossed \$19 billion in on-chain value, with private credit accounting for nearly three-quarters of that total. But the rails these assets currently run on carry the structural risks documented in Section 02.

Bitcoin-native capital markets via RGB are at an earlier stage. The protocol is proven. Tether has already begun native USDT issuance on Bitcoin via RGB. The infrastructure is being built. The opportunity for institutions is to position ahead of the migration — not after the market has priced it in.

 EVM TOKENIZATION Live today: \$19B on-chain, growing 44% CAGR	 BITCOIN / RGB Early stage: USDT live on RGB; Capital markets infrastructure in development
--	---

\$19B Tokenised RWAs on-chain today (primarily EVM) · RWA.xyz, 2025	\$19T BCG projection for total tokenised assets by 2031	\$118B+ USDT in circulation (now natively issuable on Bitcoin via RGB)	Day 1 Bitcoin asset capital markets (the infrastructure window is open now)
---	---	--	---

WHAT BITCOIN SETTLEMENT ENABLES: SELECTED USE CASES

USE CASE 01 · STABLECOINS Dollar-Denominated Settlement on Bitcoin	Tether has begun issuing USDT natively on Bitcoin via RGB, becoming the first major stablecoin to leverage Bitcoin rails. This is not a peg or a wrapped token; it is a native issuance anchored to a Bitcoin UTXO, settled with Bitcoin finality, and validated client-side. Institutions can hold, transfer, and settle USD-equivalent value without EVM bridge risk.
USE CASE 02 · PRIVATE CREDIT Loan Facilities with Programmable Logic	RGB supports complex contract schemas including waterfall distributions, seniority tranches, maturity triggers, and default provisions. All logic is validated off-chain by the participating parties. This architecture removes trustees and reconciliation lag, with settlement finality anchored to the Bitcoin block. Private credit funds can manage instruments without custodial intermediaries.

USE CASE 03 · SECURITIES Equities with Compliant Transfer Restrictions	RGB21 schemas support automated KYC/AML gating, accredited investor verification, jurisdictional limits, and lock-up periods encoded directly into the contract rather than enforced by post-trade policy. Bonds can execute coupon automation and enforce transfer restrictions cryptographically, with ownership recorded on Bitcoin.
USE CASE 04 · FUND UNITS LP Interests with Atomic Subscription	LP interests and co-investment vehicles can be issued as RGB tokens. Subscription and redemption processes execute atomically: the investor delivers payment and the fund delivers the LP token synchronously within a single transaction. Secondary trades operate identically, eliminating T+2 settlement lag and counterparty credit risk.
USE CASE 05 · SOVEREIGN National Bond Registries	Governments exploring digital bond issuance can anchor registries to Bitcoin, utilizing a ledger with an unbroken 15-year security record. The sovereign does not rely on third-party intermediaries. The contract state is held by the bondholder while Bitcoin provides absolute timestamping and settlement guarantees.

Emerging Markets Accelerate Adoption.

Outside the United States and Europe, customers are significantly less likely to hold credit cards. Where cards exist, authorization rates can run up to 30% lower than in developed markets. At the same time, these customers are twice as likely to hold crypto wallets. Stablecoins on Bitcoin are not a speculative product for this population. They are the most functional savings and payment tool available.

2× More likely to hold a crypto wallet: Global South vs. Western markets	30% Lower card authorization rates in parts of Africa, LATAM, Southeast Asia	3.5B Unbanked or underbanked adults globally · World Bank Findex 2024	\$250B Annual remittance flows to Sub-Saharan Africa and LATAM · World Bank
--	--	---	---

Companies serving Sub-Saharan Africa are 94% more likely to use stablecoins than the global sample. MENA: 69% more likely. Latin America: 69% more likely.

A Fully Integrated Capital Markets Stack.

DIBA offers a vertically integrated Bitcoin settlement framework. The wallet, marketplace, storage layer, and settlement engine are entirely unified. This architecture eliminates third-party middleware dependencies, bridge operator vulnerabilities, and external points of failure.

I

BitMask Wallet

WALLET LAYER

Non-custodial · Rust/WASM · Lightning-enabled · RGB asset support

Non-custodial institutional wallet. Self-sovereign key management, RGB asset support, and Lightning Network access. Built in Rust, compiled to WebAssembly. Private keys never leave the client device. There is no DIBA server that, if compromised, would put client assets at risk.

II

DIBA Marketplace

MARKET LAYER

Peer-to-peer atomic swap · Primary issuance · Secondary trading

Peer-to-peer atomic swap settlement. No custodial escrow, no intermediary wallet. Both legs of every trade execute in one Bitcoin transaction, or neither does. Primary issuance and secondary trading in a single interface.

III

Carbonado Storage

STORAGE LAYER

Encrypted contract state · Backed by Hut8 · Institutional SLA

End-to-end encrypted contract state storage backed by Hut8, one of North America's largest publicly traded Bitcoin miners. No central server. No single point of failure. Institutional SLA with geographic redundancy.

IV

RGB Engine

SETTLEMENT LAYER

Client-side validation · UTXO-anchored · RGB20 + RGB21 standards

Private smart contract infrastructure anchored to Bitcoin UTXOs via client-side validation. Contract state held by the asset holder. Only the cryptographic commitment touches the chain. Compatible with RGB20 (fungible) and RGB21 (non-fungible) standards.

How Institutions Should Think About Bitcoin-Native Infrastructure.

The institutional risk assessment for Bitcoin-settled capital markets differs fundamentally from EVM-based DeFi. The architectural vulnerabilities are distinct, the empirical track record is fundamentally different, and the regulatory trajectory provides superior clarity.

Technology Risk

MITIGATED

RGB has been in development since 2016 and is supported by multiple independent audits. Bitcoin's base layer carries a 15-year zero-exploit record. Contract logic is validated entirely client-side, eliminating the shared public execution environments that expose EVM chains to systemic attack.

Counterparty Risk

STRUCTURALLY ELIMINATED

Atomic swap settlement means no settlement lag, no escrow counterparty, and no custodian holding assets between execution and delivery. T+0, both legs, or no trade. That is the entire counterparty risk conversation.

Regulatory Risk

REDUCING

The GENIUS Act (U.S., 2025) created the first federal stablecoin framework, while MiCA in Europe provides a clear path for tokenised asset issuance. Furthermore, Bitcoin is explicitly recognized as a commodity by U.S. regulators, representing the clearest regulatory classification of any digital asset.

Liquidity Risk

MANAGED

Lightning Network provides 24/7 liquidity for asset transfers. Bitcoin's \$1.3 trillion market cap is the deepest liquidity pool of any digital asset. Secondary trading via DIBA Marketplace with atomic settlement removes execution risk.

Custody Risk

SELF-SOVEREIGN

BitMask Wallet is non-custodial. Private keys never leave the client device. This is not a policy position. It is the architecture.

The Gold Standard for Bitcoin-Native Finance.

DIBA targets the institutional standard for programmable bearer instruments settled on Bitcoin. The infrastructure is engineered to process the full complexity of financial securities: private, auditable, and settled on the most comprehensively tested cryptographic ledger.

RWA.xyz

\$14B

Private credit on-chain Q2 2025 —
the segment DIBA is purpose-built
for

DIBA is the only team building the complete capital markets stack natively on Bitcoin. Not on a sidechain. Not through bridges. Not through compatibility layers. From issuance to custody to settlement, every component is Bitcoin-native and cryptographically verifiable.

Base-Layer Settlement

No reliance on sidechains, bridges, or EVM compatibility layers. Every component of the stack settles directly via the Bitcoin network or Lightning. The core security assumptions of the base layer remain intact.

Vertical Integration

Wallet, marketplace, storage, and RGB engine — all owned and operated by DIBA. No dependency on third-party middleware that could break, be acquired, or be shut down.

Institutional Architecture

Built for fund managers, family offices, and sovereigns from day one. Not retrofitted from a retail product. BitMask supports institutional key management, multi-signature custody, and compliance gating at the protocol level.

Established Infrastructure

DIBA developed the initial peer-to-peer marketplace for Bitcoin-settled assets. The underlying RGB tooling, Carbonado storage layer, and BitMask wallet reflect extensive institutional-grade infrastructure development.

Compliant by Construction

Non-custodial architecture means DIBA does not hold client assets. Transfer restrictions, KYC/AML gating, and accreditation checks are encoded directly into the RGB contract logic, preventing policy evasion or post-execution settlement failures.

DIBA provides the infrastructure required to migrate traditional financial securities to Bitcoin settlement rails — delivering institutional-grade security, definitive settlement finality, and cryptographically verifiable ownership.

REQUEST A BRIEFING

For fund managers, family offices, sovereigns, and private credit issuers exploring Bitcoin-native capital markets.
